01 / SCENARIO LEDGER

Define the planning window and its limits.

DRIVER ROW

conservative / demand 8 / capacity 12

TEACHING MODEL

Delivered 8 / net 4 points, not money or a forecast.

DRIVER / CASE / CONSTRAINT

Window	One unspecified teaching window, not a calendar forecast.
Cases	Demand 8, 12 and 16; capacity fixed at 12.
Unit boundary	Teaching points are not currency or actual profit.

What can this model answer, and what remains outside its scope?

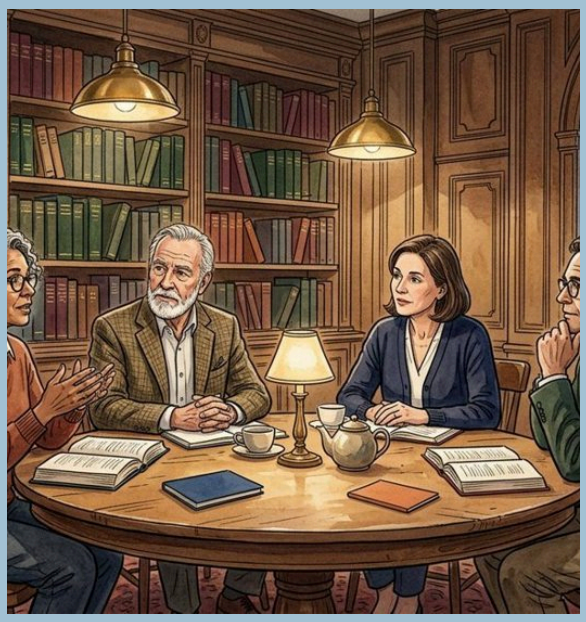

Figure 1 / fictional illustration, not evidence / curated image source in provenance.json

Edition Table is a fictional review-support concept. This ledger compares three demand assumptions within one unspecified teaching window, holding the model’s delivery capacity at twelve tasks.

The cases are not probabilities or forecasts. They illustrate how demand, a capacity ceiling and a simple point model interact. No actual period, customer pipeline, operating budget or financial statement is supplied.

Model scope

All teaching points are arbitrary and non-monetary. Keep the source register with the discussion so a reader can distinguish model arithmetic from business evidence.

02 / SCENARIO LEDGER

Name the drivers before comparing totals.

DRIVER ROW	TEACHING MODEL
baseline / demand 12 / capacity 12	Delivered 12 / net 12 points, not money or a forecast.

DRIVER / CASE / CONSTRAINT

Delivery rule	Delivered = min(demand, capacity).
Resource rule	12 fixed + 2 points per delivered task.
Net rule	4 × delivered − resource points; not monetary profit.

Which assumption has the greatest effect on interpreting the case comparison?

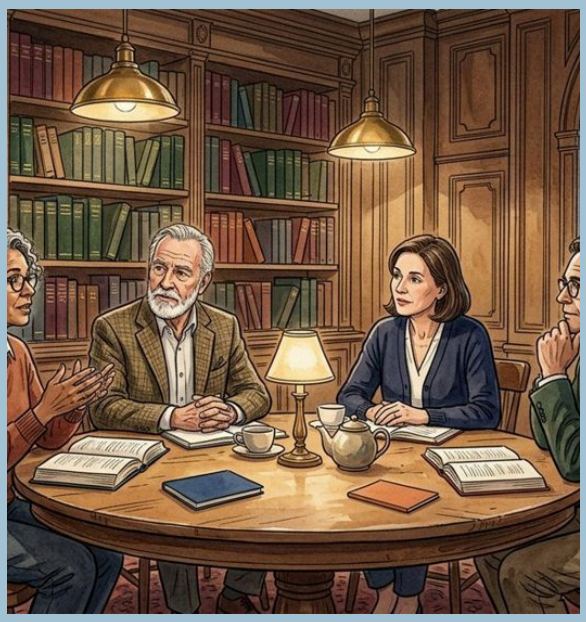

Figure 1 / fictional illustration, not evidence / curated image source in provenance.json

Delivered tasks equal the smaller of demand and capacity. Unmet tasks equal demand minus delivery when positive. Unused capacity equals capacity minus delivery.

The point model assigns four benefit points per delivered task and resource points of twelve fixed plus two per delivered task. Net points subtract resources from benefits; they are not an accounting or valuation measure.

Driver definitions

Holding a driver fixed is a modelling choice, not evidence that it is stable in real work. The model excludes timing, quality variation, payment and many other operating conditions.

03 / SCENARIO LEDGER

Read the baseline as an assumption.

DRIVER ROW	TEACHING MODEL
exploratory / demand 16 / capacity 12	Delivered 12 / net 12 points, not money or a forecast.

DRIVER / CASE / CONSTRAINT

Demand / delivery	12 requested, 12 delivered in the model.
Resource points	12 fixed + 24 variable = 36.
Net points	48 − 36 = 12; not cash or profit.

What would make full utilisation unsuitable in an actual setting?

Figure 2 / fictional illustration, not evidence / curated image source in provenance.json

In the baseline, demand is twelve and capacity is twelve. Delivery is twelve, with no unmet demand and no unused model capacity.

Benefits total forty-eight teaching points; resources total thirty-six; net points are twelve. A positive net figure only describes the authored rules. It does not demonstrate a viable business or a margin available to spend.

Baseline case

No actual demand or delivery is recorded. A fully used model capacity may conceal the absence of a reserve or the need for quality checks in a real operation.

04 / SCENARIO LEDGER

Examine the conservative demand case.

DRIVER ROW

capacity-10 / demand 12 / capacity 10

TEACHING MODEL

Delivered 10 / net 8 points, not money or a forecast.

DRIVER / CASE / CONSTRAINT

Demand / delivery	8 requested, 8 delivered.
Capacity balance	4 unused, 0 unmet.
Point arithmetic	32 benefit − 28 resource = 4 net points.

Which fixed commitment would remain if the model demand fell?

Figure 2 / fictional illustration, not evidence / curated image source in provenance.json

With demand of eight and capacity of twelve, delivery is eight. Four units of capacity remain unused in the model, and unmet demand is zero.

Benefits are thirty-two teaching points and resources are twenty-eight, leaving four net points. Lower demand does not automatically reduce the model’s fixed resource requirement. No probability or actual shortfall is attached to this case.

Conservative case

The case tests one lower demand assumption. It does not cover every adverse condition, such as a missing input, a longer task or an unplanned interruption.

05 / SCENARIO LEDGER

Inspect demand above the capacity ceiling.

DRIVER ROW

capacity-12 / demand 12 / capacity 12

TEACHING MODEL

Delivered 12 / net 12 points, not money or a forecast.

DRIVER / CASE / CONSTRAINT

Demand / delivery	16 requested, delivery capped at 12.
Unmet tasks	16 − 12 = 4; no actual backlog.
Constraint effect	Net remains 12 teaching points, as in baseline.

What would have to change before additional demand could become suitable delivery?

Figure 3 / fictional illustration, not evidence / curated image source in provenance.json

In the exploratory case, demand is sixteen but capacity remains twelve. Delivery is capped at twelve and four requested tasks remain unmet.

Benefits, resources and net points match the baseline because delivery has not increased: forty-eight, thirty-six and twelve. Higher assumed demand is not higher actual revenue, and it does not remove the delivery constraint.

Exploratory case

Unmet demand here is arithmetic, not an observed backlog or an invitation to accept work that cannot be responsibly delivered. Actual response options need appropriate review.

06 / SCENARIO LEDGER

Change one driver to inspect sensitivity.

DRIVER ROW

capacity-14 / demand 12 / capacity 14

TEACHING MODEL

Delivered 12 / net 12 points, not money or a forecast.

DRIVER / CASE / CONSTRAINT

Capacity 10	Deliver 10; net 8 points; unmet 2.
Capacity 12	Deliver 12; net 12 points; no unused units.
Capacity 14	Deliver 12; net 12 points; unused 2.

Which omitted cost would matter before acting on this sensitivity result?

Figure 3 / fictional illustration, not evidence / curated image source in provenance.json

At demand twelve, capacities of ten, twelve and fourteen produce deliveries of ten, twelve and twelve. Extra capacity above demand remains unused rather than generating extra benefit points.

Under the same point rules, net points are eight, twelve and twelve. This comparison excludes any cost of changing capacity, so it cannot justify adding resources or choosing an investment.

One-variable comparison

The source sensitivity register keeps the demand and point rules fixed. A real capacity change could alter many conditions at once.

07 / SCENARIO LEDGER

Keep the constraint visible in the plan.

DRIVER ROW

conservative / demand 8 / capacity 12

TEACHING MODEL

Delivered 8 / net 4 points, not money or a forecast.

DRIVER / CASE / CONSTRAINT

Known model limit	Delivery cannot exceed 12 tasks.
Missing operating detail	Roles, task mix, reserve and source availability.
Planning boundary	No actual workload or staffing decision authorised.

What does the capacity assumption leave unexplained?

Figure 4 / fictional illustration, not evidence / curated image source in provenance.json

A capacity number summarises an assumption. It does not explain staffing, task complexity, access needs, rework or the availability of source material.

The ledger holds capacity at twelve to expose its effect. Before applying a similar model, inspect what actually limits the work and which reserve or review conditions should be preserved. Do not infer that every unused unit is waste.

Resource constraint

No real staffing allocation or service commitment is supplied. The model cannot approve a workload or determine a safe or appropriate pace of work.

08 / SCENARIO LEDGER

Define triggers as review questions.

DRIVER ROW

baseline / demand 12 / capacity 12

TEACHING MODEL

Delivered 12 / net 12 points, not money or a forecast.

DRIVER / CASE / CONSTRAINT

Proposed trigger	A delivery constraint becomes relevant to the task.
Observation needed	Appropriate actual demand and task information.
Review route	Responsibility and response need real agreement.

What evidence would make the trigger relevant to a real decision?

Figure 4 / fictional illustration, not evidence / curated image source in provenance.json

A proposed trigger might be to review the plan when the model shows unmet demand or when actual task conditions differ from the assumptions. A trigger starts inquiry; it does not select a response automatically.

No real observation threshold or monitoring system is supplied. In practice, define the source, window and responsibility before treating a count as a reason for consequential action.

Trigger / observation / review

A modelled unmet count of four is not an actual alert. Keep the calculation separate from any eventual operational signal.

09 / SCENARIO LEDGER

Compare responses without declaring a winner.

DRIVER ROW

exploratory / demand 16 / capacity 12

TEACHING MODEL

Delivered 12 / net 12 points, not money or a forecast.

DRIVER / CASE / CONSTRAINT

Scope option	Clarify what work can be considered.
Timing option	Review whether the window assumption is appropriate.
Capacity option	Investigate actual constraints and change costs first.

Which response would require the most important missing information?

Figure 5 / fictional illustration, not evidence / curated image source in provenance.json

Possible responses include narrowing the accepted scope, changing the timing or investigating additional capacity. Each alters conditions that the simple ledger does not evaluate.

Do not choose a response solely because it raises net teaching points. Quality, permissions, accessibility, commercial terms and the effect on existing work may matter more than a model total.

Response options

The ledger is a conversation aid. It provides neither procurement approval nor a business recommendation about real money or people.

10 / SCENARIO LEDGER

Record the version and the reason for change.

DRIVER ROW

capacity-10 / demand 12 / capacity 10

TEACHING MODEL

Delivered 10 / net 8 points, not money or a forecast.

DRIVER / CASE / CONSTRAINT

Retain	Driver definitions, source rows and prior version.
Explain	Which assumption changed and why.
Boundary	Teaching arithmetic, not an actual financial forecast.

Can another reviewer reproduce the calculation and understand its limits?

Figure 5 / fictional illustration, not evidence / curated image source in provenance.json

A version record should retain the demand cases, capacity rule, point definitions and the question the comparison was meant to support. Preserve previous assumptions when changing a driver.

This version contains three authored cases and three sensitivity rows. It reports no actual operating or financial result. A revised model should identify what changed in the evidence rather than only displaying a new total.

Model revision record

If the unit, window or delivery definition changes, reconsider comparisons with earlier versions. Similar-looking figures may no longer mean the same thing.
